Introduction

- Axial piston pumps with swashplate design for reliable operation and long life.
- Special design for closed loop application.
- Pressure up to 420 bar. Rated speed up to 1800 r/min higher speeds possible.
- Rotating and pressure loaded parts are pressure balanced.
- Oversize shaft and shaft bearings.
- Large charge flow rates for low system temperature.
- Wide range of available integrated charge and pilot pressure pump combinations.
- Standard available transmission circuits with integrated valves and filters to build complete closed loop system for charge flow and flushing.
- Fast response times.
- For new product applications use TVW. Use TVX 130-250 for service replacement only.

AVAILABLE DISPLACEMENT SIZES

- For a combination of two or more units fill out this Combination Model Code.
- Start with the biggest size unit for the first displacement.
- For each unit included in this combination, a separate model code must be chosen. Use the form on page 5.
- Character 26 to 39 will be P/N of the combination. This number will be defined by Eaton and provided in the order acknowledgement.

24 25 Fourth Control Type

- 00** – No Control (for Fixed Displacement Only)
- DF** – Pressure Compensator
- LR** – Power Control
- ES** – Electric Motor Control
- HG** – Handwheel
Displacement Control
- FE** – Screw Adjustment
Displacement Control

FE, HG Manual Adjustment Displacement Control

"X" Series – Closed Loop

FE The FE-control is a displacement control where the pump flow is adjusted by a screw.

HG The HG-control is a displacement control where the pump flow can be adjusted by handwheel.

The maximum (and/or minimum) flow can be limited by a spacer inside the control cylinder (position no. 13 in modelcoding, options 4, 5 or 6 in combination with

customer adjustment speculation position 47-50 for the set values). The setting must be defined before ordering and cannot be modified during operation.

Electric Motor Displacement Control ES

"X" Series – Closed Loop

The unit is used for flow adjustment. It has a three phase electric servo motor, worm gearing and a switch box with 4 or (optional) 8 limit switches for different positions. A potentiometer is also available.

The response times from zero to maximum depends on the chosen ratio and the (fixed) speed of the servo motor (this means that once the control is defined and built the response times are not variable during operation).

No Pressure / Power Limiter possible!

Explosion protection versions are also available.

As an additional option the maximum (and/or minimum) flow can be limited by a spacer inside the control cylinder

(position no. 13 in model coding, options 4, 5 or 6 in combination with customer adjustment speculation position 47-50 for the set values). The setting must be defined before ordering and cannot be modified during operation.

Response Time Table

THEORETICAL RESPONSE TIME (SEC) FOR MAXIMUM DISPLACEMENT CHARACTER IN MODEL CODE POS. 30

Size	066 / 090		130 / 180		250		
Freq. Hz	50	60	50	60	50	60	
Fast	7	6	18	15	15	13	M
Medium	24	20	35	29	30	25	N
Slow	38	32	54	45	48	40	P

Response time from 0 to +Qmax or 0 to - Qmax

Pressure Signal Displacement Control DP

"X" Series – Closed Loop

The output flow of the pump is proportional to the pilot pressure.

A separate pilot oil circuit is necessary.

From this, the control pressure is reduced to the desired set value by means of a suitable pressure control valve (with P-T line) and throttle in P-line 0.8 Ø (0.03 in).

To work in both directions, a solenoid valve is needed to switch the pilot flow from A to B (pos. 30 in model coding, option "K").

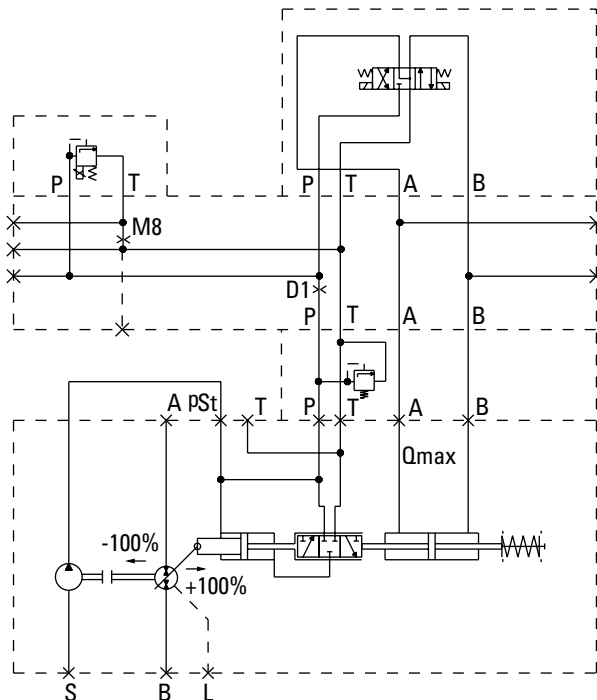

The DP-control can be used for stepless flow control with standard requirements for dynamic and precision.

No feedback signal is needed, an optical indicator recommended (pos. 24 in model coding, option "V").

A pilot oil filter can be mounted in-line between pump and control (pos. 42 in model coding, option "V" or "E").

Pressure limiter or power limiter override not available (for such and other options please refer to PVW-Series).

As an additional option the maximum (and/or minimum) flow can be limited by a spacer inside the control cylinder (position no.13 in model coding, options 4, 5 or 6 in combination with customer adjustment speculation position 47-50 for the set values). The setting must be defined before ordering and cannot be modified during operation.

TVX Response Times DP - Control

SIZE	RESPONSE TIME (SEC) WITH 12 L/MIN PILOT OIL FLOW	
	(Standard)	Pilot Pressure pSt [bar]
066/090	0,7	60
130/180	0,9	60
250	1,1	60

The output flow of the pump is proportional to the pilot pressure

Example for TVXS

DP Control

“X” Series – Closed Loop

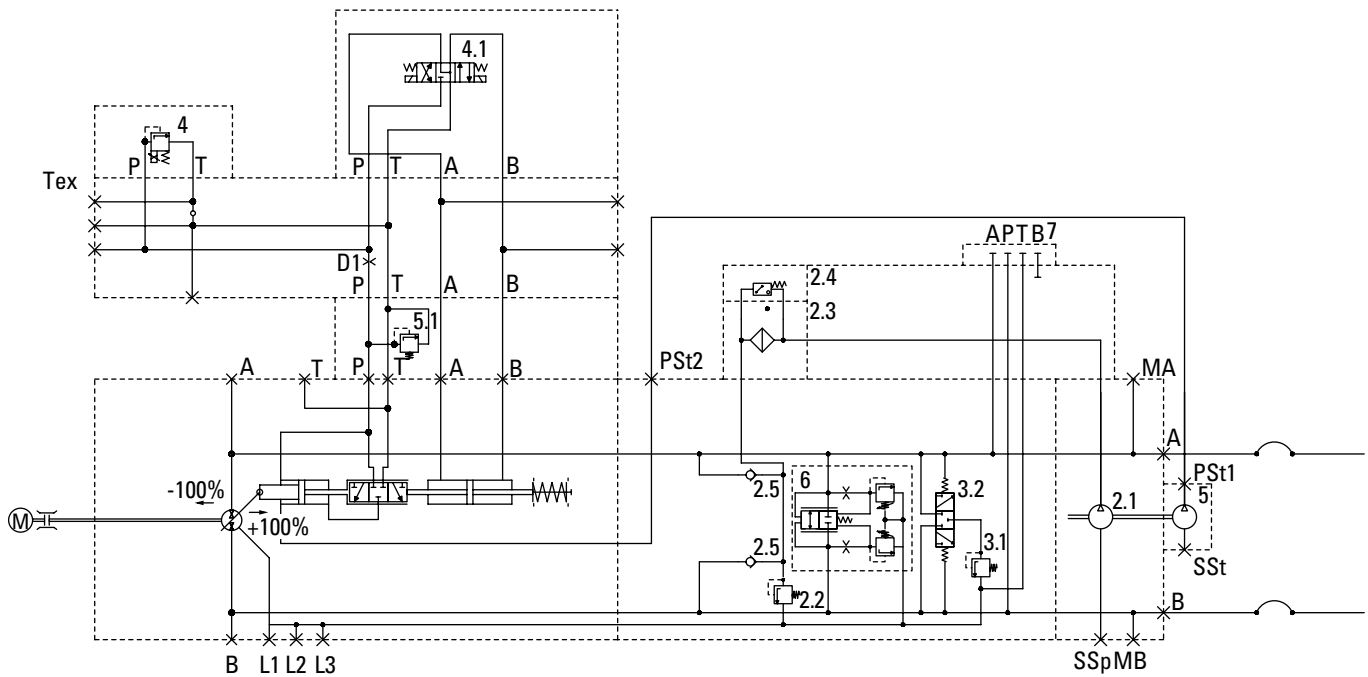

The example shows a TVXS-130 pump with DP-control and complete transmission circuit, for over-center operation

(with solenoid valve 24V DC) with charge oil filter with electrical indicator, but without pilot oil filter.

Other model coding also possible due to some variations which cannot be seen in the circuit diagram (seal material, main drive shaft end).

Possible model coding for such pump:

TVXS-130M04R000TP1R01SVVA20DPK00C000000000000H000000010.

Proportional Valve Displacement Control SP

"X" Series – Closed Loop

The SP control operates a hydrostatic drive and works without throttle losses within electrically adjustable limits. This is done by controlling delivery flow with electrical swashplate angle feedback (electrical closed-loop control).

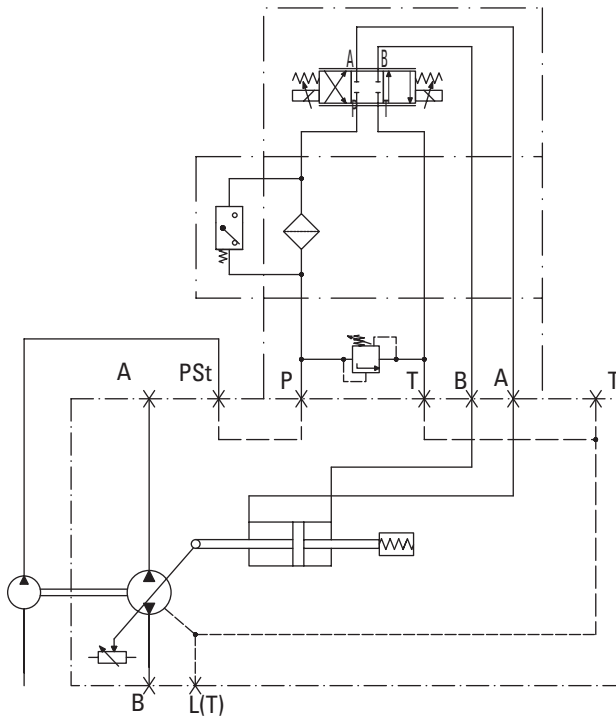

All control values are recorded as an electrical signal and lead back to the control card. The proportional valve and servo piston transform the output signal of the control card to the desired setting.

This results in a very precise and dynamic control.

Pressure limiter override available on request. Power limiter override not available (for such and other options please refer to TVW series).

As an additional option the maximum (and/or minimum) flow can be limited by a spacer inside the control cylinder (position no.13

in model coding, options 4, 5 or 6 in combination with customer adjustment speculation position 47-50 for the set values). The setting must be defined before ordering and cannot be modified during operation.

Application Data

INSTALLATION POSITION DRAIN PIPING

Shaft pointed upwards

Shaft pointed downwards

Application Data - Fluid Recommendations

Case Flushing Requirements

A check valve must not be used in the drain pipe. The drain pipe must interminate below the oil level in the reservoir.

For all other conditions with low pressure <20 bar (<300psi) and low flow (<10% of Qmax) case flushing is required.

For operation with special fluids HFB and HFC, case flushing is recommended.

Flushing Flow

Flushing flow via the pump case should be >1% of maximum pump flow. Maximum flushing flow depends on case pressure.

Notes:

- All listed ratings are based on the use of a good quality fluid.
- Alternative fluids have a reduced tolerance for contamination over petroleum-base fluids. Good filtration is therefore critical.
- The pumps will provide exceptional life when used with a good quality clean fluid at the pump ratings specified for that fluid.

Fluids

Pumps in the catalog are primarily designed to operate with conventional petroleum-based hydraulic oil.

Alternative fluids and restrictions:

- Fluid maintenance is critical to the durability of all hydraulic components, and particularly so with hydraulic pumps. This becomes even more of a factor when alternative fluids are used. All types of alternative fluids require extensive maintenance in order to maintain proper levels of water content, acidity, viscosity and contamination.

Fluid Cleanliness

These pumps are rated for anti-wear petroleum fluids with a contamination level of 18/15/13 per ISO 4406. Operation in fluids with higher contamination levels than this is not recommended and may reduce the life of the pump components. Fluids other than petroleum, severe

service cycles, or temperature extremes are cause for adjustment of these codes. Please contact your Eaton representative for special duty cycle recommendations.

Eaton pumps, as well as any variable displacement piston pumps, will operate with apparent satisfaction in fluids up to the rating specified here.

Experience has shown, however, that pump and hydraulic system life is not optimized with high fluid contamination levels (high ISO cleanliness codes).

Proper fluid condition is essential for long and satisfactory life of hydraulic components and systems. Hydraulic fluid must have the correct balance of cleanliness, materials, and additives for protection against wear of inclusion of air.

Essential information on the correct methods for treating hydraulic fluid is included in Eaton publication 561- "Vickers Guide to Systemic Contamination Control"-

available from your local Eaton distributor.

In this publication, filtration and cleanliness levels for extending the life of axial piston pumps and other system components are listed. Included is an excellent discussion of the selection of products needed to control fluid condition.

Ordering Procedure

When ordering please specify full model designation of items required; see "Model Codes" section of this catalog.

Note the following:

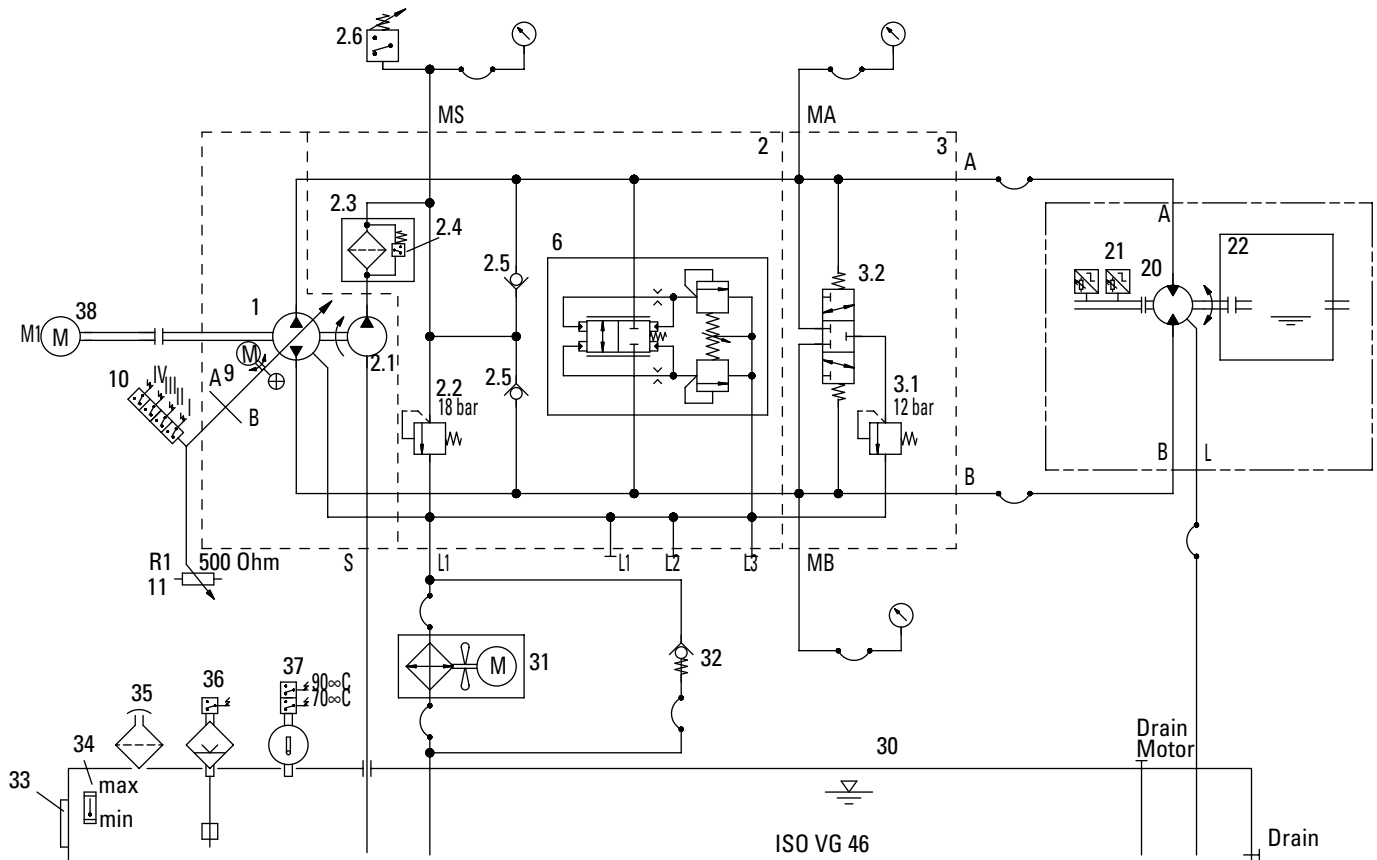

- Designation of variable displacement pumps must include the supplementary designation of the required control.

FLUIDS

TYPE	CLASSIFICATION	MAX PRESSURE BAR	MAX SPEED RPM	RECOMMENDED SEAL MATERIAL	MAX OPERATING TEMPERATURE °C	BEARING LIFE
Oil in Water Emulsion	HFAE	Not Rated				0%
Water in oil Emulsion	HFB	250	1800	Fluorocarbon	49	50%
Water Glycol	HFC	250	1800	Fluorocarbon	49	25%
Phosphate Ester	HFDR	350/420	1800	Fluorocarbon	66	100%
Polyol Ester	HFDU	350/420	1800	Fluorocarbon	66	100%

Application Information

Description of Closed Loop Transmission with Electric Motor Displacement Control

The schematic enclosed shows a typical heavy duty hydrostatic transmission. The pump and motor are the main components. The filter, reservoir, heat exchanger and oil lines make up the rest of the system.

The function of these components is described below:

The Pump

The pump generates the flow of high pressure oil. The typical transmission employs a variable displacement pump. The variable displacement feature allows

the amount of oil pumped to be varied. And the amount of oil pumped controls the motor's output speed. For example, when the pump's displacement is zero, no oil is pumped and the transmission's output shaft is at rest. Conversely, maximum displacement produces maximum speed. The direction of high pressure flow can also be reversed; doing so reverses the direction the output shaft rotates. An external energy source, called the prime mover (usually an electrical motor), turns the input shaft of the pump.

The Motor

The motor uses the high pressure oil flow from the pump to produce transmission output. The high pressure oil comes to the motor through one of the high pressure lines. It enters the motor, turns the output shaft, then returns to the pump. The pump and motor in the drawing are connected in a closed-loop circuit.

Important:

Remember, the pump generates flow, and the load on the motor's output shaft causes resistance to that flow. That resistance to flow is what creates the high pressure. Therefore, the oil flowing in the lines that connect the pump and motor is called "high pressure flow."

The pump and motor in the drawing are contained in separate housings. This configuration provides maximum flexibility in design and transmission installation.

Application Information

(cont.)

The Charge Pump

The charge pump generates a low pressure oil flow that has three functions. First, it supplies a continuous flow of oil through the pump and motor cases. This "case flow" keeps the transmission cool. In the drawing, the case flow goes from the motor to the pump, then to the heat exchanger and back to the reservoir. Second, the charge pump keeps the high pressure lines filled. This ensures that the transmission remains primed even after extended periods of running in neutral. Finally, charge pump flow provides back pressure in the high pressure lines when the transmission is in forward or reverse. The charge pump contains a relief valve that helps maintain the pressure of the low pressure oil flow.

The charge pump bolts onto the pump and its input shaft connects with the input shaft of the pump. The charge pump inlet receives oil from the reservoir.

The Valve Block

The valve block contains a two-sided high pressure relief valves, a shuttle valve and a charge pressure relief valve.

The high pressure relief valve protects the transmission from pressures that are too high. The shuttle valve and charge pressure relief valve direct excess charge pump flow into the pumps case. This case flow cools the pump. The valve block bolts directly to the pump.

The Heat Exchanger, Reservoir, Filter, and Oil Lines

The heat exchanger, reservoir, filter and oil lines are all necessary for heavy duty transmission operation. The heat exchanger connects between the case flow outlet and the reservoir. It cools the oil before it enters the reservoir. The heat exchanger must be fitted with a by-pass valve that opens when case drain pressure gets too high. The by-pass valve is especially important during cold starts when the oil is thick. The reservoir supplies a steady flow of oil to the charge pump inlet. It also provides room for the oil to expand as it gets hot and for entrapped air to escape. The filter is installed between the charge pump outlet and the valve block. It removes contaminants from the oil.

The oil lines provide passage ways for the oil flowing among the transmission components. They must be strong enough to withstand the pressures generated and may be rigid or flexible.

Description of Operation

A hydrostatic transmission is a dynamic system that operates through a wide range of conditions. Nevertheless, this wide operating range can conveniently be divided into three basic modes: neutral, forward and reverse.

The schematics and their accompanying explanations will help you visualize what's going on inside the transmission during each of the operating modes.

Important: As you study the following flow descriptions, remember that in all modes of operation, the input shaft of the pump is being turned by an external power source.

Neutral

The hydrostatic transmission is in neutral when the variable pump's displacement is zero. With zero displacement, no high pressure oil is pumped to the motor and its output shaft is stopped.

Putting the control signal in the neutral position centers the swashplate. With the swashplate centered the pistons don't reciprocate as the cylinder barrel is rotated and no high pressure oil is pumped.

The charge pump, which is connected to the input shaft, pumps oil in all modes of transmission operation. In neutral, it takes cooled, filtered oil from the reservoir and fills the system. Charge pump flow passes through the check valves in the pump's end cover and fills the pump pistons, the high pressure lines and the motor's pistons. This oil flow is intended to make up for internal leakage and keep the circuit primed.

After the high pressure circuit has been primed, the charge pump pressure opens the charge pressure relief valve located in the charge pump. This directs the charge pump flow through the pump case and back to the reservoir. This oil flow flushes and cools the pump.

The forward mode and the reverse mode are similar, so they will be grouped and called the forward! reverse mode.

Application Information

(cont.)

Forward/Reverse

The hydrostatic transmission is in the forward/reverse mode when flow in the high pressure circuit causes the motor shaft to rotate.

Flow in the high pressure circuit is created by tilting the pump's variable swashplate from its center or neutral, position. With the swashplate tilted, the pistons reciprocate as the cylinder barrel rotates and flow is generated.

The swashplate may be tilted to either side of center.

Tilting it one way generates flow that makes the transmission go forward. And tilting it the other way reverses flow and the motor shaft rotates in the opposite direction.

Besides controlling direction, the swashplate angle also controls output speed. Swashplate angle affects speed by changing the pump's displacement. The

largest swashplate angle produces the largest displacement and the fastest motor speed.

The Electrical Motor Displacement Control circuit varies the swashplate angle by turning a spindle directly fixed to the servo piston. According to the direction of rotation of the control motor, the spindle turns and the swashplate is tilt until the motor is switched off (for more detailed explanations refer to separate description of the Electrical Motor Displacement Control).

Charge pump flow that is not used by the control circuit passes through the end cover check valve into the bw pressure side of the loop. There it provides back pressure to the motor pistons.

The spring centered shuttle valve, located in the pump's valve block, moves to connect the low pressure side of the loop to the charge pressure

relief valve. When back pressure gets high enough the charge pressure relief valve, in the valve block, opens and charge pump flow enters the the pump case.

Case flow flushes the pump cases and helps keep the transmission cool. The charge pressure relief valve typically has a lower setting than the charge pressure relief valve in the charge pump. This is so case flow will begin at the motor, go to the pump, and return to the reservoir.

The charge pressure relief valve in the charge pump opens when the transmission is in neutral and the shuttle valve is centered.

The 2-side high pressure relief valve opens to connect the high pressure side of the loop to the low pressure side if the motor stalls and the pressure gets too high. This valve works in forward and in reverse direction.

Last remark

All valves, relief valves and switches, are adjusted at the test bench according customers specification and needs and must not be misplaced without special knowlegde of the hydraulic system!
